Non-Reacting Gas Mixtures

Introduction

- homogeneous gas mixtures are frequently treated as a single compound rather than many individual constituents

- the individual properties of inert gases tend to be submerged, such that the gas behaves as a single pure substance

- eg. - air consists of oxygen, nitrogen, argon and water vapour. But dry air can be treated as a simple gas with a molar mass of $28.97\ kg/kmole$

- equations can be derived to express the properties of mixtures in terms of the properties of their individual constituents

- it is assumed that each constituent is unaffected by the other constituents in the mixture

P-V-T Relationships for Ideal Gas Mixtures

Amagat Model (law of additive volumes)

- the volume of a mixture is the sum of the volumes that each constituent gas would occupy if each were at the pressure, P and temperature, T, of the mixture

T, P	T, P		T, P
m_A	m_B	remove	$m_C = m_A + m_B$
n_A	n_B	→	$n_C = n_A + n_B$
V_A	V_B	partition	$V_C = V_A + V_B$

- the volume that n_i moles of a component i would occupy at P and T is called the partial volume, V_i

$$V_i = \frac{n_i \mathcal{R} T}{P}$$

1

The volume of the gas mixture is equal to the sum of the volumes each gas would occupy if it existed at the mixture temperature and pressure.

$$V = \sum_{i=1}^{j} V_i$$

Dalton Model (law of additive pressures)

- the pressure of a mixture of gases is the sum of the pressures of its components when each alone occupies the volume of the mixture, V, at the temperature, T, of the mixture

$$
\boxed{\begin{array}{c} V, T \\[2ex] m_A, n_A, P_A \end{array}}
+
\boxed{\begin{array}{c} V, T \\[2ex] m_B, n_B, P_B \end{array}}
=
\boxed{\begin{array}{c} V, T \\[1ex] m_C = m_A + m_B \\ n_C = n_A + n_B \\ P_C = P_A + P_B \end{array}}
$$

- for a mixture of ideal gases the pressure is the sum of the partial pressures of the individual components

The pressure of a gas mixture is equal to the sum of the pressures each gas would exert if it existed alone at T and V.

By combining the results of the Amagat and Dalton models i.e. (1) and (2), we obtain for ideal gas mixtures

$$\frac{P_i}{P} = \frac{V_i}{V} = \frac{n_i}{n}$$

Therefore, Amagat's law and Dalton's law are equivalent to each other if the gases and the mixture are ideal gases.

Mixture Properties

Extensive properties such as U, H, c_p, c_v and S can be found by adding the contribution of each component at the condition at which the component exists in the mixture.

$$U = \sum U_i \;=\; \sum m_i u_i = m \sum X_i u_i = mu$$

$$=\; \sum n_i \overline{u}_i = n \sum Y_i \overline{u}_i = n\overline{u}$$

where $\overline{u}$ is the specific internal energy of the mixture per mole of the mixture.

$$
\boxed{
\begin{aligned}
u &= \sum X_i \, u_i \\[6pt]
h &= \sum X_i \, h_i \\[6pt]
c_v &= \sum X_i \, c_{v_i} \\[6pt]
c_p &= \sum X_i \, c_{p_i} \\[6pt]
s &= \sum X_i \, s_i
\end{aligned}
}
$$

Changes in internal energy and enthalpy of mixtures

$$u_2 - u_1 \;=\; \sum X_i (u_2 - u_1)_i = \int_{T_1}^{T_2} c_v \, dT = c_v (T_2 - T_1)$$

$$h_2 - h_1 \;=\; \sum X_i (h_2 - h_1)_i = \int_{T_1}^{T_2} c_p \, dT = c_p (T_2 - T_1)$$

$$s_2 - s_1 \;=\; \sum X_i (s_2 - s_1)_i = c_p \ln \frac{T_2}{T_1} - R \ln \frac{P_2}{P_1}$$

These relationships can also be expressed on a per mole basis.

Entropy Change Due to Mixing of Ideal Gases

- when ideal gases are mixed, a change in entropy occurs as a result of the increase in disorder in the systems

- if the initial temperature of all constituents are the same and the mixing process is adiabatic

3

– temperature does not change

– but entropy does

$$\Delta S \;=\; -\left(m_A R_A \ln \frac{P_A}{P} + m_B R_B \ln \frac{P_B}{P} + \cdots\right)$$

$$=\; -\sum_{i=1}^{j} m_i R_i \ln \frac{P_i}{P}$$

$$=\; -\mathcal{R}\sum_{i=1}^{j} n_i \ln Y_i$$

Psychrometrics

- studies involving mixtures of dry air and water vapour

- used in the design of air-conditioning systems, cooling towers and most processes involving the control of vapour content in air

- for $T \leq 50°C$ $(P_{sat} \leq 13\,kPa)$ $\Rightarrow$ $h \approx h(T)$

  - water vapour can be treated as an ideal gas

Definitions

Moist Air

- a mixture of dry air and water vapour where dry air is treated as if it were a pure component

- the overall mixture is given as $\Rightarrow$ $P = \dfrac{mRT}{V}$

Total Pressure

$$P = P_a + P_w$$

$$P_a = \frac{m_a R_a T}{V}$$

$$P_w = \frac{m_w R_w T}{V}$$

where P_a is the partial pressure of air and P_w is the partial pressure of water vapour. Typically $m_w \ll m_a$.

Relative Humidity - ϕ

$$\phi = \frac{P_w(T)}{P_{sat}(T)} = \frac{\text{vapour pressure at the prevailing T}}{\text{saturation pressure at the prevailing T}}$$

If $P_w = P_{sat}(T)$ the mixture is said to be saturated.

Specific Humidity (Humidity ratio) - ω

$$\omega = \frac{m_w}{m_a} = \frac{\text{mass of water vapour}}{\text{mass or air}}$$

$$= \frac{\tilde{M}_w n_w}{\tilde{M}_a n_a} = \frac{\tilde{M}_w (P_w V / \mathcal{R} T)}{\tilde{M}_a (P_a V / \mathcal{R} T)}$$

$$= \left(\frac{\tilde{M}_w}{\tilde{M}_a} \right) \left(\frac{P_w}{P_a} \right)$$

$$= 0.622 \left(\frac{P_w}{P_a} \right)$$

In addition ω can be written as

$$\omega = 0.622 \left(\frac{P_w}{P_a} \right) = 0.622 \left(\frac{P_w}{P - P_w} \right) = 0.622 \left(\frac{\phi P_{sat}}{P - \phi P_{sat}} \right)$$

which can be rearranged in terms of relative humidity

$$\phi = \frac{P \omega}{P_{sat} \left(\omega + \frac{\tilde{M}_w}{\tilde{M}_a} \right)} = \frac{P \omega}{P_{sat} (\omega + 0.622)}$$

Dry Bulb Temperature - the temperature measured by a thermometer placed in a mixture of air and water vapour
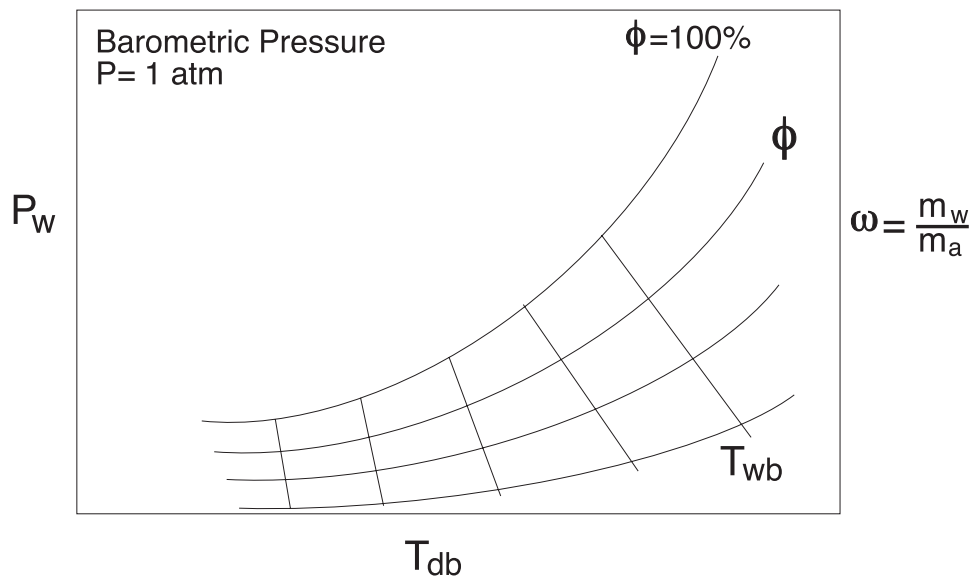

Wet Bulb Temperature

6

- thermometer surrounded by a saturated wick

- if air/water vapour mixture is not saturated, some water in the wick evaporates and diffuses into the air → cooling the water in the wick

- as the temperature of the water drops, heat is transferred to the water from both the air and the thermometer

- the steady state temperature is the wet-bulb temperature

Sling Psychrometer - a rotating set of thermometers one of which measures wet bulb temperature and the other dry bulb temperature. T_{DB} and T_{WB} are sufficient to fix the state of the mixture.
The Psychrometric Chart

where the **dry bulb** temperature is the temperature measured by a thermometer place in the mixture and the **wet bulb** temperature is the adiabatic saturation temperature.

An Adiabatic Saturator

How can we measure humidity?

T$_1$, P$_1$

① air/water mixture

ϕ_1 = ?
ω_1 = ?

long pool @ T$_3$

③ saturated air/water mixture

ϕ_3 = P$_w$ / P$_{sat}$ = 1

T$_3$ = adiabatic saturation temperature
$\cong$ wet-bulb temperature

② saturated make up water

T$_2$ = T$_3$

- the adiabatic saturator is used to measure humidity

- two inlets, single exit device through which moist air passes

- air-water mixture of unknown humidity enters at a known pressure and temperature

- if air/water mixture is not saturated, ($\phi < 100\%$), some water from the pool will evaporate

- the energy required to evaporate the water comes from the moist air $\rightarrow$ mixture temperature decreases

- for a sufficiently long duct, the moisture exits with $\phi_3 = 1$

- the temperature of the exiting mixture is called the adiabatic saturation temperature

Adiabatic Saturator Analysis

Conservation of Mass

$$\dot{m}_{a,1} = \dot{m}_{a,3} \qquad \text{air} \qquad (1)$$

$$\dot{m}_{w,1} + \dot{m}_{w,2} = \dot{m}_{w,3} \qquad \text{water} \qquad (2)$$

Conservation of Energy

$$(\dot{m}h)_{a,1} + (\dot{m}h)_{w,1} + (\dot{m}h)_{w,2} = (\dot{m}h)_{a,3} + (\dot{m}h)_{w,3} \qquad (3)$$

8

By definition

$$\omega_1 = \left(\frac{\dot{m}_w}{\dot{m}_a}\right)_1 \qquad (4)$$

$$\omega_3 = \left(\frac{\dot{m}_w}{\dot{m}_a}\right)_3 \qquad (5)$$

From (2) and (1)

$$\left(\frac{\dot{m}_{w,2}}{\dot{m}_{a,1}}\right) = \left(\underbrace{\frac{\dot{m}_{w,3}}{\dot{m}_{a,1}}}_{\dot{m}_{a,3}}\right) - \left(\frac{\dot{m}_{w,1}}{\dot{m}_{a,1}}\right) = \omega_3 - \omega_1$$

Dividing (3) by $\dot{m}_{a,1}$ and noting $m_{a_1} = m_{a_3}$ and $\dfrac{m_{w_2}}{m_{a_1}} = \omega_3 - \omega_1$

$$h_{a,1} + \omega_1\, h_{w,1} + (\omega_3 - \omega_1)\, h_{w,2} = h_{a,3} + \omega_3\, h_{w,3} \qquad (6)$$

$$\omega_1 = \frac{(h_{a,3} - h_{a,1}) + \omega_3\,(h_{w,3} - h_{w,2})}{(h_{w,1} - h_{w,2})}$$

If we assume:

i) air is an ideal gas and $(h_{a,3} - h_{a,1}) = c_{p_a}(T_3 - T_1)$

ii) $(h_{w,3} - h_{w,2}) = h_g - h_f = h_{fg}(T_3)$

iii) $h_{w,1} \approx h_g(T_1)$

iv) $h_{w,2} = h_f(T_2) = h_f(T_3)$

then we can write ω_1 as a function of T_1 and T_3 only

$$\omega_1 = \frac{c_{p_a}(T_3 - T_1) + \omega_3\, h_{fg}(T_3)}{h_g(T_1) - h_f(T_3)}$$

Aside: Since $h_f \ll h_g$ very little is lost if the denominator is approximated as $h_{fg}(T_1)$

During the adiabatic saturation process, the vapour pressure increases and the temperature decreases; so the adiabatic saturation temperature is higher than the dew point temperature and lower than the dry bulb temperature. For the limiting case of a saturated mixture, the dry bulb, dew point and adiabatic saturation temperature are the same.

Equation 6 can be written as

$$h_1^* + \underbrace{(\omega_3 - \omega_1)\, h_{\ell,2}}_{negligible} = h_3^*$$

where

$$h^* = h_a + \omega\, h_w$$

Therefore $h_1^* \approx h_3^*(T_{wb})$. The lines of wet bulb temperature and h^* coincide on the psychrometric chart. Since h_3^* is solely a function of T_{wb}, lines of h_1^* are proportional to T_{wb}.
