

Week 12: Lecture 2**Enthalpy of Combustion**

- for various types of fuels the enthalpy of formation is not always known
 - the chemical composition of most fuels may vary from batch to batch
 - generally not tabulated
- enthalpy of combustion is an experimental alternative to enthalpy of formation
 - defined as the difference between the enthalpy of the products and the enthalpy of the reactants where complete combustion occurs at a given temperature and pressure

$$Q = \sum (mh)_P - \sum (mh)_R = H_P(T_P) - H_R(T_R)$$

$$Q = \sum (n\bar{h})_P - \sum (n\bar{h})_R = \underbrace{\bar{H}_P(T_P) - \bar{H}_R(T_R)}_{H_{RP}}$$

- when enthalpy of formation data is available for all products and reactants the above equation can be used
- otherwise a calorimeter must be used to measure the enthalpy of combustion
- $+ve Q \Rightarrow$ endothermic reaction
- $-ve Q \Rightarrow$ exothermic reaction

Heating Value

- the heating value of a fuel is a positive value equal to the magnitude of the enthalpy of combustion

Week 12: Lecture 2

- two values are used
 - HHV: higher heating value - obtained when all the water formed by combustion is a liquid
 - LHV: lower heating value - obtained when all the water formed by combustion is a vapour
- the HHV exceeds the LHV by the energy required to vaporize the liquid formed

$$HHV = LHV + (mh_{fg})_{H_2O}$$

Adiabatic Flame Temperature

- under adiabatic conditions the maximum temperature attained by the products when combustion is complete is called the adiabatic flame or adiabatic combustion temperature

$$H_P(T_{ad}) = H_R(T_R)$$

$$\sum_P n_e (\bar{h}_f^o + \Delta \bar{h})_e = \sum_R n_i (\bar{h}_f^o + \Delta \bar{h})_i$$

$$\sum_P n_e (\Delta \bar{h})_e = \sum_R n_i (\Delta \bar{h})_i + \sum_R n_i \bar{h}_{f_i}^o - \sum_P n_e \bar{h}_{f_e}^o$$

where

- n - obtained from reaction equation
- $\bar{h}_{f_i}^o$ - from tabulated data
- $\Delta \bar{h}$ - from tables or calculated knowing T_R

Therefore all terms on the right hand side can be evaluated. While the left hand side accounts for the change in enthalpy from T_{ref} to T_{ad} , which is unknown. The procedure requires iteration.

The temperature for the products is assumed. We then keep trying until we get agreement with the RHS. A typical value of $T_{ad} \approx 2300 \text{ K}$ for most hydro carbon fuels
